

There is an XML weather API accessible from
http://www.ilmateenistus.ee/ilma_andmed/xml/forecast.php?lang=eng

Build a Spring-Boot (<https://spring.io/guides>) based web-application (single page) that consumes the API and displays a relevant weather forecast to the user in a human-readable format.

- What info to show and how to solve the UI is up to you — as long as the user gets relevant weather info.
- No limitations are set on the front-end framework, so use whatever framework you want and design the page however you see fit.
- The application should use Gradle as the build environment and should be easy to compile and run.
- After building the application, please send us the source code for evaluation.
